GLOSSARY

| | |
|---------------------------------|---|
| Artificial Materials | Man-made structures (e.g., rafts, barges, docks, buildings, deterrents); may be permanent or temporary, floating or fixed, or may form part of a bank. Includes synthetic or other materials used to stabilize slopes |
| Bank | The engineered or natural outer perimeter of a Liquid Impoundment Facility; slope may be shallow or steep, may be vegetated or non-vegetated. A sparsely vegetated bank would be considered vegetated if it provides sufficient cover to act as an attractant to birds |
| Bitumen Mat(s) | Floating bitumen |
| Chick | Young local bird that has not yet developed the ability to fly |
| Emergent Vegetation | Vegetation rooted in shallow water and can be seen above the water surface; usually found along edges or in shallows in a Liquid Impoundment Facility. Flooded upland vegetation is not emergent vegetation |
| Flat | Terrain with minimal slope (typically less than 5% or 3 degrees); may be vegetated or non-vegetated (gravel, sand, mud, coke) |
| Guild, Non-target | Species that peck, fly, glean, stoop/depredate, or scavenge (except gulls) as their primary means of foraging; includes raptors, game birds such as grouse, woodpeckers, and passerines (including ravens) |
| Guild, Target; or Waterbird | Species that wade, dabble, or dive in water as their primary means of foraging; includes ducks, geese, shorebirds, grebes, loons, cranes, cormorants, swans, pelicans, coots, rails, gulls, terns, herons, and kingfishers |
| Incidental Observation | An oiled bird, live or dead, detected outside of a formal bird survey or mortality search procedure |
| Island(s) | A relatively small area of exposed terrain surrounded by water where birds may perch, rest, build nests, or forage. May be vegetated or non-vegetated (gravel, sand, mud, coke); may be permanent or temporary, floating (muskeg mats) or fixed. Does not include floating logs |
| Liquid Impoundment Facility | A structure, including its banks if present, that holds process-affected water, and may or may not contain bitumen |
| Migrant | A bird observed once during bird surveys. Birds that cannot be confirmed to be migrants are to be characterized as unknown |
| Mortality | For the purposes of this monitoring program, includes only oiled dead birds (oiled birds discovered dead, and oiled birds captured and euthanized). Birds that are not oiled and found dead, are reported according to site procedures |
| OSBCMP | Oil Sands Bird Contact Monitoring Program |
| Other Habitat Type | Includes ice cover, woody debris, flooded upland vegetation, and any habitat type not previously described |
| Resident | A bird that is observed in or around the LIF over multiple days; includes adults and chicks. Birds that cannot be confirmed to be residents are to be characterized as unknown |
| Species of Conservation Concern | Species designated as Endangered, Threatened, or Special Concern under the Canadian <i>Species at Risk Act</i> , Committee on the Status of Endangered Wildlife in Canada or the Alberta <i>Wildlife Act</i> , or listed within Alberta as At Risk, May Be at Risk, or Sensitive (Appendix A) |

| | |
|-----------|--|
| Upland | Habitats outside of the perimeter (the bank) of a Liquid Impoundment Facility that are not associated with the Bird Mortality Risk posed by LIF contents; a bird landed on upland habitat is ignored during a bird survey unless it is oiled (live or dead), and recorded as an incidental observation |
| Waterbird | See "guild, target" |

1.0 INTRODUCTION

The Oil Sands Bird Contact Monitoring Program (OSBCMP) was initiated in 2011 in response to heightened awareness of avian mortalities as a consequence of contact with bitumen on water within tailings facilities. Participation in the program by companies with oil sands mining operations is a regulatory requirement, expressed through regulatory approval conditions and/or authorized Bird (or Waterfowl) Protection Plans submitted by operators as part of the *Environmental Protection and Enhancement Act* approval condition(s).

The OSBCMP Protocol (Protocol) was initially designed to detect avian landings, flyovers, and mortalities related to bitumen contact at oil sands liquid impoundment facilities (LIFs¹). Each year, the Protocol was updated in response to the findings of the preceding year, and to address logistical challenges encountered during monitoring (St. Clair 2012, 2013, 2014; OMEI 2015). This 2016 Protocol is the next iteration, incorporating minor procedural changes based on analyses of the data acquired to date, within the constraints of the logistical challenges associated with working in and around the large and small LIFs at the five mining sites.

As in previous years, the Protocol includes two primary monitoring components, the bird survey and the mortality search, executed at LIFs where the risks of bird contact and/or mortality are highest. These are supplemented with a quick scan procedure applied to LIFs with Low Bird Mortality Risk, and as in previous years, an incidental observation procedure to record oiled bird observations outside of the primary components.

LIF risk is determined through the application of a risk model, the outcome of which determines the allocation of effort to the various types of LIFs at each of the mining sites. Bird surveys and mortality searches are to be conducted at tailings facilities and LIFs at which Bird Mortality Risk is ranked as High.

The program has five objectives that were established at the initiation of the program:

1. Provide an estimate of bird contacts and mortalities on ponds (LIFs) containing process-affected waters.
2. Provide an estimate of bird contacts on ponds containing freshwater.
3. Develop a standardized monitoring program for all oil sands mine operations to provide comparable data across LIFs, sites, seasons, and years.
4. Identify species at risk (species of conservation concern²) that have been affected through contact on LIFs containing process-affected waters.
5. Provide direction on adaptive management for long-term monitoring and bird deterrent programs.

¹ The term "liquid impoundment facility" is used in place of "pond".

² The term "species at risk" refers specifically to species categorized at defined population sensitivity levels, not broadly to include all species listed within provincial and federal documents. In 2015, this term is changed to "species of conservation concern" to more broadly encompass species at some level of provincial and/or national concern. Species of conservation concern are listed in Appendix B.

The second objective (to provide an estimate of bird contacts on ponds containing freshwater) was fulfilled from 2011 to 2014, and monitoring of freshwater ponds was discontinued in 2015.

2.0 SCHEDULE OF DELIVERABLES (FIELD PROGRAM)

The schedule of deliverables in Table 1 provides an overview of deliverables, due dates and parties responsible for components of the OSBCMP field programs. The sections that follow provide details associated with each deliverable.

Table 1: Schedule of Deliverables – OSBCMP Field Programs

| Deliverable | Date | Responsibility |
|--|--|--|
| Provide LIF names, survey station coordinates, electronic tablet identifiers, and names and initials of bird survey personnel to Program Manager | April 10 | Site operator or designate |
| Prepare LIF images, with UTM grids for bird surveyors and mortality searchers | April 16 | Site operator or designate |
| On maps, identify areas where bird may be attracted and where there is an elevated risk of bird mortality | April 16 | Site operator or designate |
| Calculate the distance required for transect-based mortality searches | April 16 | Site operator or designate |
| Identify the number of fixed-radius scans and/or small LIF searches required | April 16 | Site operator or designate |
| Bird surveyors and mortality searchers to have completed pre-season training sessions | April 16 | Site operator or designate and Program Manager |
| Establishment of bird survey stations and delineation of bird survey area boundaries | April 16 | Site operator or designate |
| Survey area habitat characterization | Start of monitoring and every two weeks thereafter | Bird surveyors |
| Bird surveyors to complete an intra-season IOV based training session | April 16 to July 6 | Site operator or designate and Program Manager |
| Bird surveyors to complete an intra-season IOV based training session | July 25 to October 31 | Site operator or designate and Program Manager |
| Delivery of satellite imagery to the Program Manager | October 31 | Site operator or designate |

Each survey station is to be given a unique code (a 4 to 10 character string preferred) that will be used consistently through the season. Survey station names should be kept as short as possible to facilitate inclusion of survey station names in maps, tables and data figures.

Each operator is to acquire one high-resolution image of their site each year, showing the LIFs included in the OSBCMP procedures. The image is to be taken at about the same time each year (variances due to cloud cover are acceptable), preferably during June or early July. This image is to be used to define the characteristics of each LIF and survey area, using GIS coupled with ground-based observations.

3.0 HABITAT DEFINITIONS

The definition of the LIF is inclusive of all features within the top of the constructed banks of the LIF. In the absence of an engineered or natural bank (i.e., the landform slopes gradually away from the open water without an obvious bank), the LIF limit is designated to be either at an apparent transition to upland vegetation or 50 m from the edge of open water, whichever is less. While a 50 m delineation of a LIF edge may be considered arbitrary, it is likely that habitat(s) contained within this area will have the most impact on bird landings in the LIF, and it is necessary to delineate a LIF limit and survey area boundaries for the purposes of monitoring and data analyses. Habitats are defined in Table 2 and illustrated in Figure 1. This represents a grouping of some habitats that were separately defined in the 2015 program, and addresses the often artificial or difficult to discern distinctions between similar habitat types within LIFs.

Table 2: Habitat Definitions (2016)

| 2016 Habitat Type | Habitat Type(s) Included |
|-------------------------|--|
| Open Water | Open Water |
| Flat/Bank Vegetated | Vegetated Flat Vegetated Bank |
| Island Vegetated | Vegetated Island |
| Emergent Vegetation | Emergent Vegetation |
| Flat/Bank Non-vegetated | Gravel, Sand, Mud Flats Coke Flat Non-vegetated Bank |
| Island Non-vegetated | Non-vegetated Island |
| Artificial Materials | Bank constructed of Artificial Materials Artificial Structure |
| Bitumen Mat | Bitumen Mat |
| Other | Woody debris, flooded upland vegetation, and other habitat types not described above. Must describe in comments section of data entry form |

4.0 LIQUID IMPOUNDMENT FACILITY INCLUSION/EXCLUSION CRITERIA AND RISK MODEL

Each LIF at a mine site is to be examined using the following inclusion and exclusion criteria, followed by application of the risk model to examine LIFs that are neither included nor excluded by the criteria. This process will identify the LIFs that are to be included in the OSBCMP bird survey and mortality search programs. Some LIFs excluded from these programs will be included in the quick scan procedure.

New LIFs, and LIFs to which process-affected water becomes a component of the effluent, would be either explicitly included in the OSBCMP (i.e., tailings facilities), or evaluated using the risk model. Evidence of bird mortality due to bitumen content at a LIF would also be cause to re-evaluate the LIF against the exclusion criteria and/or using the risk model in subsequent years.

No changes to the inclusion criteria, exclusion criteria, or risk model have been made for the 2016 program year.

**Figure 1: Habitat Components in a Liquid Impoundment Facility
(Cross Section; vertically-exaggerated)**

4.1 Liquid Impoundment Facility Inclusion and Exclusion Criteria

4.1.1 LIF Inclusion Criteria

Tailings facilities are the primary target of monitoring programs within the OSBCMP, with the majority of landings and bitumen-related mortalities occurring within these facilities. The size of the tailings facilities, their contents (including bitumen), and the bird contact and mortality data collected from 2011 to 2015 justify the inclusion of these facilities in the ongoing OSBCMP monitoring programs. These large facilities were the original target of the monitoring program arising out of the bird landing events in 2008 and 2010.

4.1.2 LIF Exclusion Criteria

The LIF exclusion criteria are presented in Table 3, and will be used in assessing LIF inclusion for the 2016 program. Data acquired from the period of 2013 to 2015 (inclusive) are to be used in the evaluation of LIFs using these criteria, and the results documented. LIFs not explicitly excluded by application of these criteria are to be evaluated using the risk model.

The 2015 bird survey data, normalized to a per survey basis, are to be used to evaluate the LIF against the 2nd criterion (landings of target guild species of ≤ 0.10 per survey in preceding two years). Following the 2016 season, revision to an area-based normalization (birds per ha) would be appropriate.

Table 3: Small Liquid Impoundment Facility Exclusion Criteria

| LIF Characteristics | Exclusion Criteria |
|-----------------------------------|---|
| Open water area | ≤1.5 ha |
| Target guild landing observations | Landings of target guild species of ≤0.10 per survey in preceding two years |
| LIF-associated mortalities | Mortalities of ≤1/year due to contact with bitumen in the LIF |
| Industrial setting | LIF is within 100 m of active industrial operations, staging area(s) and/or roads |
| Human activity | Daily human presence, observed birds reported per site reporting requirements |

4.2 Liquid Impoundment Facility Risk Model

The risk model is to be applied to LIFs not explicitly included or excluded by the above criteria. The model operates through a series of steps (Figure 2) to derive a Bird Mortality Risk (High or Low) associated with the LIF. In addition to tailings facilities (included per the criteria above), LIFs rated as having a High Bird Mortality Risk are included in the bird survey and mortality search procedures of the OSBCMP. The application of the risk model to each LIF evaluated is to be documented.

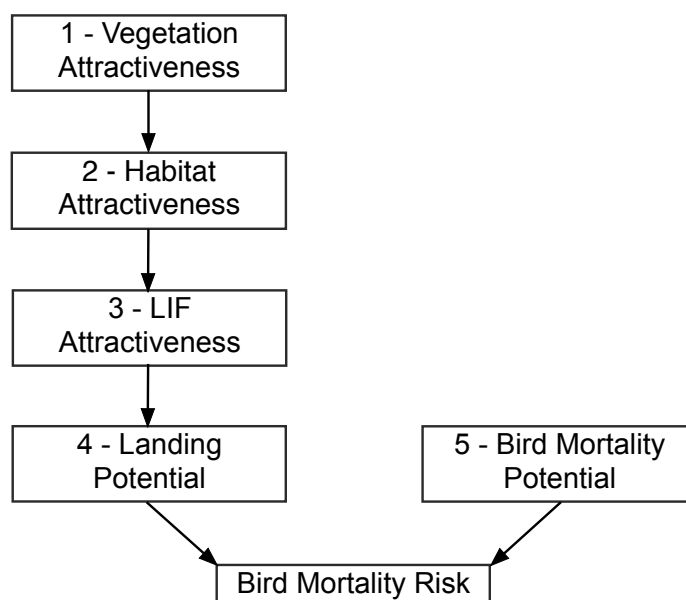

Figure 2: Determination of Bird Mortality Risk using the Oil Sands Bird Contact Monitoring Risk Model

STEP ONE: Vegetation Attractiveness

The presence of vegetation in, on and around the LIF is an attractant to birds. The complexity of vegetated habitats is considered in this step of the model.

Determine if vegetation is present on the perimeter (flats and/or banks) of the LIF, and if vegetated islands and/or emergent vegetation is present. Woody debris, deterrent devices and artificial structures do not constitute islands, and are ignored. These features are then used to derive a Vegetation Attractiveness rating of High, Moderate or Low, using the following matrix:

| 1 – Vegetation Attractiveness | | Vegetated Island &/or Emergent Vegetation in LIF | |
|------------------------------------|---------|---|--------|
| | | Present | Absent |
| Vegetated Flat &/or Vegetated Bank | Present | HIGH | HIGH |
| | Absent | MODERATE | LOW |

STEP TWO: Habitat Attractiveness

The presence of flats is an attractant, particularly for species in the wader and gull guilds. Flats may be composed of gravel, sand, mud and/or coke. Non-vegetated islands (exposed sand, rocks or other perching substrates) are also attractants, and may be used as resting areas. Complex flats (varying topography, varying composition) that abut open water and are near to cover are ranked as having a High attractiveness. Large, expansive flats without topographical complexity, composed primarily of a single material, and are not proximal to open water or vegetative cover are ranked as having a Low attractiveness. Flats between these two conditions are rated as having Moderate attractiveness. Characterization of flat complexity and the influences associated with proximity to open water and/or nearby cover requires professional judgment and knowledge of bird habitat preferences.

Using the Vegetation Attractiveness rankings derived in Step One together with the attractiveness ratings for flats, derive a Habitat Attractiveness rating of High, Moderate or Low:

| 2 – Habitat Attractiveness | | Complexity of Non-vegetated Flats &/or Non-vegetated Islands | | |
|-------------------------------|----------|---|----------|----------|
| | | High | Moderate | Low |
| Vegetation Attractiveness (1) | High | HIGH | HIGH | MODERATE |
| | Moderate | HIGH | MODERATE | LOW |
| | Low | MODERATE | LOW | LOW |

STEP THREE: LIF Attractiveness

Large areas of open water are an attractant, therefore, the area of open water is included in the evaluation of LIF attractiveness. Open water areas of 5 ha and larger are considered to have a high degree of attractiveness, particularly for divers that require larger ponds for take-off. Open water areas of 1.5 ha or less (a cut-off incorporated from the 2014 OSBCMP Protocol) are less attractive, while open water areas of 1.5 to 5 ha are considered to be moderately attractive. Using the results from the Habitat Attractiveness matrix (Step Two) together with the open water area, derive a LIF Attractiveness rating of High, Moderate or Low, using the following matrix:

| 3 – LIF Attractiveness | | Open Water Area | | |
|----------------------------|----------|-----------------|-------------|----------|
| | | >5 ha | 1.5 to 5 ha | ≤1.5 ha |
| Habitat Attractiveness (2) | High | HIGH | HIGH | MODERATE |
| | Moderate | HIGH | MODERATE | LOW |
| | Low | MODERATE | LOW | LOW |

STEP FOUR: Landing Potential

Although the LIF Attractiveness rating is likely to identify the majority of LIFs that will attract waterbirds, data acquired to date can be used to ensure that LIFs attractive to birds for reasons not considered Steps One to Three are properly evaluated. The landed bird observation data (target guilds) from the preceding two years, for LIFs that have been included in the program, provide the means for this evaluation.

For evaluation of a LIF for which bird survey data are available, the maximum number of landings per survey in the previous two years is to be used. For a LIF with more than one survey station, the survey station with the highest bird landings per survey is to be used. For a LIF not included in the OSBCMP to-date, assign a target guild landings per survey of 0.05 to 1.5 for this step. This assignment results in the Landing Potential being derived on the basis of habitat alone for previously un-monitored LIFs. For this step, the 2015 bird survey data, normalized to a per survey basis, are to be used. Following the 2016 season, an evaluation of the cutoffs using an area-based normalization (birds per ha) from 2015 and 2016 would be appropriate. Using the results from the LIF Attractiveness matrix (Step Three) together with the greater of the number of target guild landings per bird survey from the previous two years, derive the Landing Potential (High, Moderate, Low) for the LIF using the following matrix:

| 4 – Landing Potential | | Target Guild Landings per Survey (Greater of the Preceding Two Years) | | |
|---------------------------|----------|--|--------------|----------|
| | | >1.5 | 0.05 to 1.5* | <0.05 |
| LIF Attractiveness (3) | High | HIGH | HIGH | MODERATE |
| | Moderate | HIGH | MODERATE | LOW |
| | Low | MODERATE | LOW | LOW |

* A LIF not included in the OSBCMP program to-date is assigned this category.

STEP FIVE: Bird Mortality Potential

A Bird Mortality Potential rating is to be derived independently from the LIF Attractiveness rating procedure (Steps One to Four). The Bird Mortality Potential rating is based on two factors: the presence/absence of bitumen in the effluent stream to the LIF, and the observation of a bird mortality (including captured and euthanized birds) associated with the LIF in the preceding two years. Only mortalities that can be associated with contact with bitumen in the LIF are considered in this analysis. Determine if bitumen is or can be present on the LIF surface, and if one or more LIF-related mortalities have been observed in the preceding two years. For each LIF, determine the Bird Mortality Potential rating of High, Moderate or Low, using the following matrix:

| 5 – Bird Mortality Potential | | Bird Mortality in Past Two Years due to Contact with Bitumen in LIF | |
|------------------------------|-----|--|----------|
| | | Yes | No |
| Surface Bitumen Present | Yes | HIGH | MODERATE |
| | No | HIGH | LOW |

STEP SIX: Bird Mortality Risk

A matrix combining the Landing Potential (Step Four) with the Bird Mortality Potential (Step Five) is used to define the Bird Mortality Risk (High or Low) associated with each LIF:

| Bird Mortality Risk | | Bird Mortality Potential (5) | | |
|-----------------------|----------|--|--|--|
| | | High | Moderate | Low |
| Landing Potential (4) | High | High Risk Bird Survey & Mortality Search | High Risk Bird Survey & Mortality Search | Low Risk Quick Scan &/or Incidental Observations |
| | Moderate | High Risk Bird Survey & Mortality Search | High Risk Bird Survey & Mortality Search | Low Risk Quick Scan &/or Incidental Observations |
| | Low | High Risk Bird Survey & Mortality Search | Low Risk Quick Scan &/or Incidental Observations | Low Risk Quick Scan &/or Incidental Observations |

5.0 TRAINING AND PROTOCOL SUPPORT

The Program Manager is responsible for ensuring that training on the procedures in this Protocol is provided to site personnel by April 16. Each operator must ensure that field personnel acquire the appropriate site-level training and orientations necessary to begin monitoring on April 16. Training dates, times, and locations will be determined in consultation with site operators, taking into account crew shift schedules.

Monitoring crews are responsible for knowing how to use the tools required to perform the procedures within this protocol (compass, GPS, range finder, tablets and tablet forms, optics, bird identification guides).

The Program Manager will provide protocol support personnel, who will provide site-level protocol training and procedural oversight through the season. This will replace the training sessions held mid-season, and focus efforts on addressing issues and questions arising in the procedures, and provide guidance on how to execute the procedures when facing unique situations not explicitly covered in this protocol.

6.0 BIRD SURVEYS

6.1 Overview of the Bird Survey Procedure

The bird survey procedure applies to the LIFs determined to have a High Bird Mortality Risk. The purpose of the bird surveys is to document the number and species of birds landed within each survey area, as observed from a ground-based survey station.

Table 4 provides an overview of the 2016 bird survey procedure, and summarizes changes since 2013.

Table 4: Evolution of the Bird Survey Procedures (2013 to 2016)

| Item | 2013 (St. Clair et al. 2013) | 2014 (St. Clair et al. 2014) | 2015 (OMEI 2015) | 2016 |
|-----------------------------------|---|---|---|--|
| LIF inclusion | Survey all LIFs that were included in previous Protocol | As in 2013, but small LIFs without landings or mortalities surveyed once per week | LIFs defined as having a High Bird Mortality Risk included in the bird survey procedure | As in 2015 |
| LIF characteristics | Describe LIF characteristics for vegetation, islands, beach and bitumen (bitumen cover estimated to nearest quartile), analyses of satellite image by GIS | As in 2013, but conducted four times per year | LIF characteristics described using a satellite image, analysed by GIS coupled with ground-based observations | As in 2015 |
| Number of survey stations per LIF | Open water area ≤ 150 ha = 1 station 151 to 500 ha = 2 stations 501 to 1,000 ha = 3 stations >1,000 ha = 4 stations, one per quadrant | As in 2013 | As in 2014, except quadrant requirement removed for liquid impoundments >1,000 ha | As in 2015 |
| Survey season | Spring and fall monitoring periods: April 16 to July 6, and July 25 to October 31 | As in 2013 | As in 2014 | April 16 to October 31, inclusive (mid-season break eliminated) |
| Survey schedule | LIFs monitored 7 days per week. Freshwater ponds monitored 2 days (surveys) per week | LIFs of high priority monitored 6 days per week. LIFs of low priority monitored once per week. Freshwater ponds monitored 2 days per week | LIFs with High Bird Mortality Risk monitored 6 days per week | LIFs with High Bird Mortality Risk monitored 3 days per week |
| Comparison day | None | One day per week selected by each operator, used for training, IOV, missed surveys, data QA/QC | As in 2014, except restriction on selection of comparison day by each operator relaxed | Comparison day eliminated |
| Survey method | Time-based survey of birds landed and flying over LIFs within the survey area | As in 2013 | Ground-based census of birds landed at LIFs within the survey area. No flyover observations | As in 2015 |
| Survey station naming | QR code signs to identify the location of the survey station | As in 2013 | As in 2014, however, new QR code signs not required for any new stations | QR codes no longer required. Survey stations to be named using unique codes. Sites to mark survey stations at their discretion |
| Alternate survey stations | Alternate survey stations were used when the primary station was temporarily inaccessible | As in 2013 | Alternate survey stations no longer used. Missed surveys are completed on the comparison day | As in 2015, missed surveys completed on the next available day (only one survey per day per survey station is permitted) |

| Item | 2013 (St. Clair et al. 2013) | 2014 (St. Clair et al. 2014) | 2015 (OMEI 2015) | 2016 |
|-----------------------------------|---|---|--|---|
| Survey area | Survey area includes the water, shore that could be reached at any time of the year by changing water levels, and air below 100 m within a 500 m radius of the survey station | As in 2013 | Survey area delineated based on a 500-m radius from the survey station. Habitats within the survey area characterized | As in 2015 |
| Survey duration | Open water area ≤150 ha = 10 min >150 ha = 30 min | As in 2013; use of a stopwatch | Sufficient to confidently identify and count (census) all visible landed birds in the survey area, minimum survey duration of 5 minutes and maximum duration of 30 minutes | As in 2015 |
| Bird inclusion | Include birds that contact the shore area in addition to those landed on water | All species, landed and flying within the survey area. Gulls not considered a target guild (post-season data analyses treated gulls as a target guild). Distinguish between birds as being on water or between current waterline and high water mark and whether that area is wet or dry. High water mark includes any area with visible bitumen or water residue | All landed birds within the survey area. Habitat within which bird landed recorded | As in 2015 |
| Flyovers | Report flyovers that occur within 100 m immediately above survey areas | As in 2013 | Flyovers removed from bird survey procedures | As in 2015 |
| Requirements for single observers | Use of voice recorder to avoid looking away from LIF to record data, or a stopwatch to suspend monitoring during data recording | Function on tablet to stop scan clock when single observers are recording data | Monitoring can be completed by single or multiple observers | As in 2015 |
| Bird hazing | Not discussed | Hazing not permitted during a bird survey, only species of conservation concern in imminent danger hazed after survey complete | Hazing permitted at conclusion of survey, immediately if a bird is in imminent danger of bitumen contact. Hazing prior to or during a bird survey invalidates the survey | As in 2015 |
| IOV | U of A visited all sites several times during each of spring and fall | Operator personnel conducted intra-site IOV sessions | IOV procedure incorporated into training program | IOV's removed from protocol |
| Training | Attendance at U of A webinar | Operator-level Protocol training | Classroom and field sessions for monitoring personnel to understand the Protocol and to minimize observer variability | Program Manager to provide Protocol training prior to April 16, and protocol support through the season |

| Item | 2013 (St. Clair et al. 2013) | 2014 (St. Clair et al. 2014) | 2015 (OMEI 2015) | 2016 |
|----------------------------------|--|---|--|--|
| Data Submission and Verification | Submit data via electronic forms, paper forms used only on an interim or emergency basis | Where permitted and within site safety requirements, data entered in an electronic form and sent to the server. Data verification on a 2-week cycle. Paper forms used when required by site safety restrictions | Tablet forms for data recording and transmission. Paper forms to be derived by site operators for use when site safety restrictions limit use of electronic devices. Data submission required weekly | As in 2015, except that electronic data recording systems other than tablets may be used, providing data are formatted for integration into the regional dataset |

6.2 Survey Stations and Survey Areas

6.2.1 Establishing a Survey Station

Survey station locations are to be selected for best viewing bird activity on the LIF, within site safety and access restrictions. The number of survey stations to be established on a LIF varies with LIF size (Table 5), and is the same as in previous years. For LIFs with multiple stations, stations should maintain a minimum 200-m separation between survey areas.

Table 5: Number of Survey Stations per LIF

| Open Water Area (ha) | Number of Survey Stations |
|-----------------------------|----------------------------------|
| ≤150 | 1 |
| 151 to 500 | 2 |
| 501 to 1,000 | 3 |
| >1,000 | 4 |

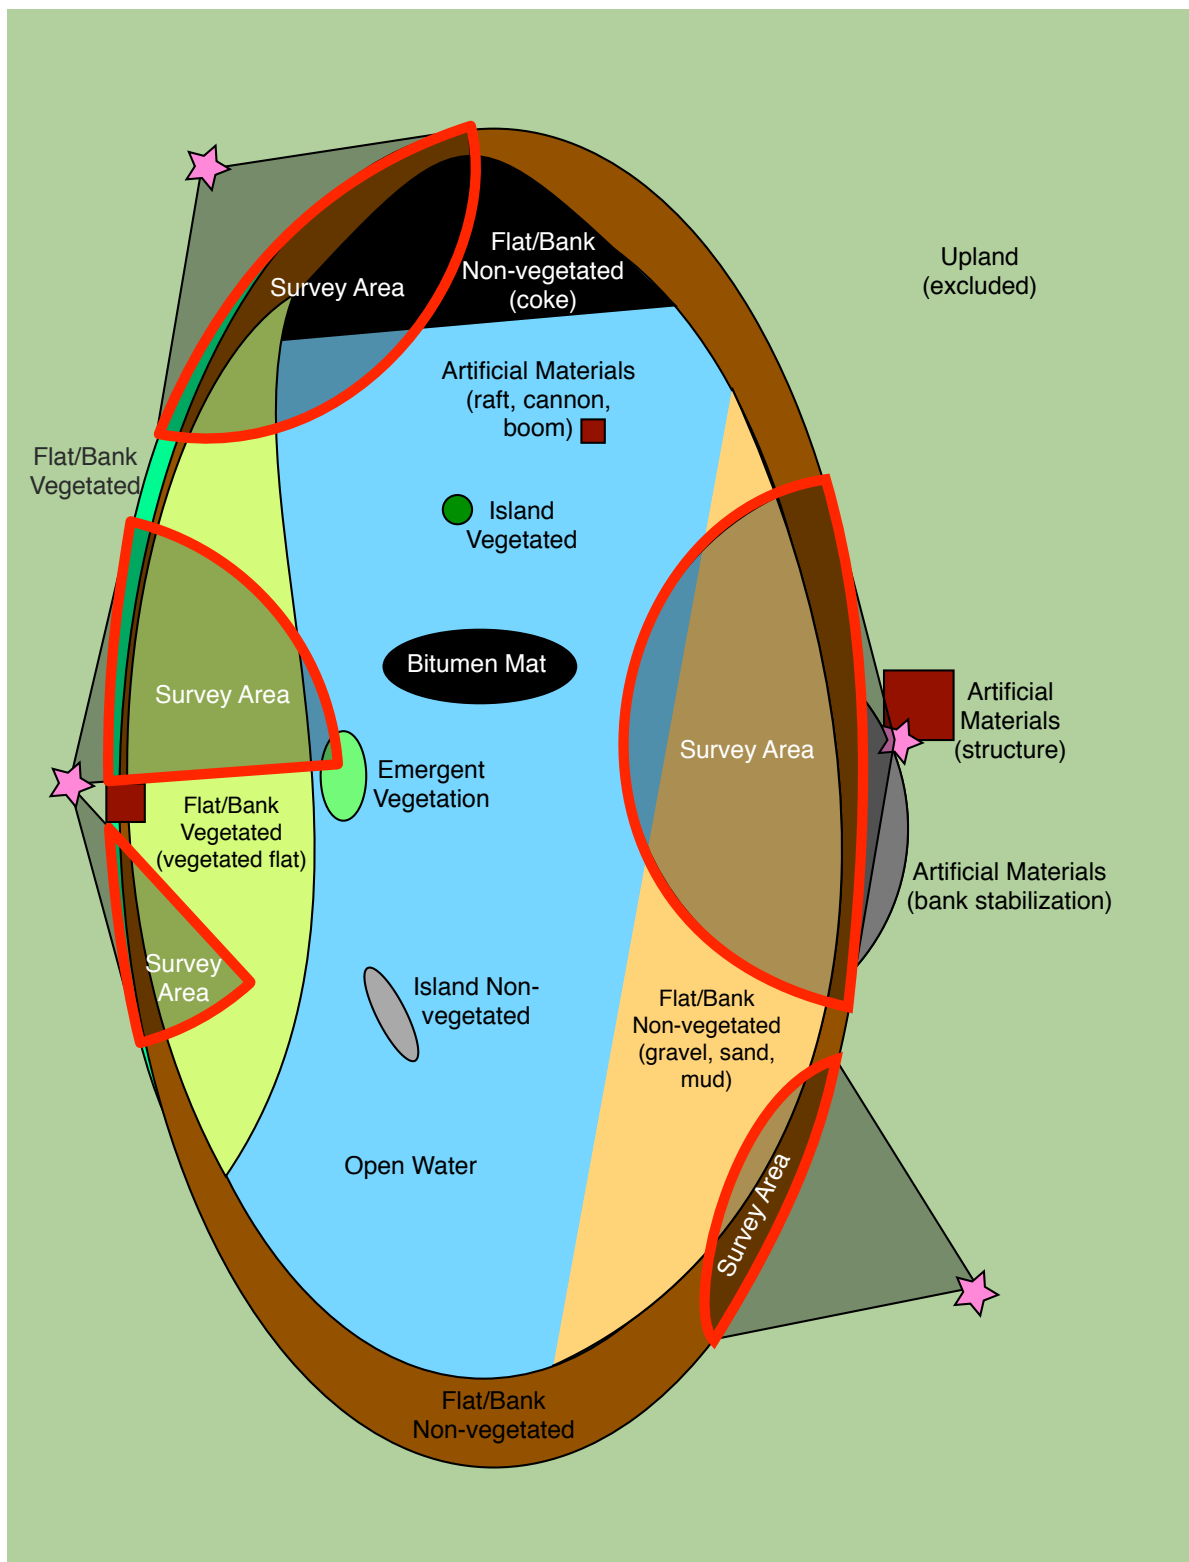

6.2.2 Survey Area Delineation and Habitat Characterization

Each survey station is to be given a unique code (a 4 to 10 character string preferred) that will be used consistently through the season. Survey station names should be kept as short as possible to facilitate inclusion of survey station names in maps, tables and data figures.

Survey stations should be established within 200 m of the bank (or edge) of the LIF, as the survey area shrinks rapidly with increasing distance of the setback beyond 200 m (Figure 3). The survey area is defined as the visible LIF area within a 500-m radius of the survey station. The boundaries of each survey area are to be delineated prior to the start of the monitoring season, and must be held constant throughout the 2016 monitoring program.

Topography may interfere with visibility of some areas that would otherwise be included within the survey area. Examples include a tall bank that shields a portion of the LIF from observers; in this instance, the survey area boundary begins at the point where the survey area comes into view (Figure 4). In this example, habitats included in the survey area include all those within the LIF visible between the survey station and the 500-m radius defining the survey area. The area between the survey limit (the lower sight line) and the top of the nearest bank is not visible to observers, and data on the presence of landed birds in this zone are not to be collected.

In the event that an obstacle blocks visibility to a portion of the survey area, personnel may delineate the survey area in two parts, as illustrated on the left of Figure 3. Although in two parts, this is to be considered a single survey area for bird survey and habitat assessment data collection. Alternatively, survey personnel may walk a short distance to one or both sides of the obstacle to gain visibility, and providing that the boundaries of the survey area are understood and consistently applied, a bird survey conducted across the entire survey area (including the portion behind the obstacle) is a valid survey. Bird survey personnel taking this approach must neither violate site safety requirements (i.e., move into unsafe areas), nor create a disturbance that significantly affects the number of birds in the survey area.

**Figure 3: Delineation of Survey Areas
(based on a 500-m radius from the Survey Station)**

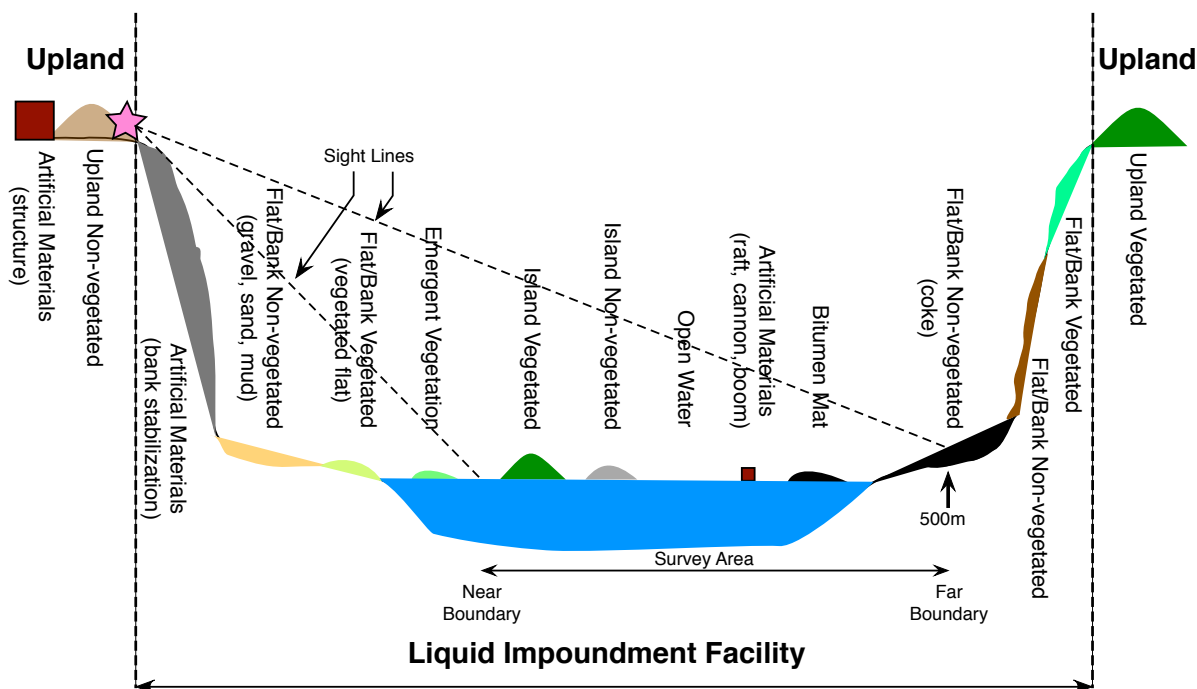

Figure 4: Survey Area Delineation to Accommodate Field of Vision Constraints (cross-section)

The habitat composition within each survey area is to be characterized every two weeks through the spring and fall monitoring seasons. The first habitat composition assessment is to be completed within the first week of monitoring in each of the spring and fall sessions. Habitat assessments should also be conducted on the last day of observations from a station being abandoned (if possible), and on the first day of observations at a new station.

The habitat assessment data requirements are presented in Table 6. Coverage of each habitat type present in the survey area estimated to the nearest percent. These data will provide information on the approximate abundances of the various habitat types within each survey area, and an indication of the variability of these abundances during the monitoring seasons.

Each operator is to acquire one satellite image of each LIF included in the bird survey procedure, per year. The image is to be taken at about the same time each year (variances due to cloud cover are acceptable), preferably during June or early July. This image is to be used to define the characteristics of each LIF and survey area, using GIS coupled with ground-based observations.

Table 6: Habitat Assessment Data Form

| | | |
|--|--|----------------|
| LIF Name | | |
| Station Code | | |
| Date | | |
| Surveyed by | | |
| Field of View - Left and Right Compass Bearings | | |
| Distance to Near and Far Survey Area Boundaries | Note if standing at the Near survey area boundary, or if the Near boundary is in front of or behind the observer | |
| Habitat | Percent Area¹ | Comment |
| Open Water | | |
| Flat/Bank Vegetated | | |
| Island Vegetated | | |
| Emergent Vegetation | | |
| Flat/Bank Non-vegetated (includes gravel, sand, mud, coke) | | |
| Island Non-vegetated | | |
| Bitumen Mat | | |
| Artificial Materials (structures, floating or fixed, bank stabilization) | | |
| Other (describe) ² | | |
| Notes³ | | |

Notes:

¹ Must total to 100%

² Must describe other habitats such as ice cover, woody debris and flooded upland in notes

³ Notes providing information on other factors that might affect the presence of birds

6.2.3 Replacement of a Survey Station

If a survey station becomes unsafe, inaccessible, or the survey area becomes irrelevant to monitoring birds, a replacement survey station is to be established, its survey area boundaries delineated, and survey area habitats delineated following the procedures in Section 6.2.1. The replacement station is to be given a new (unique) survey station name or code.

If it becomes necessary to amend the survey area boundaries, a new survey station name or code assigned, even if the survey station itself does not move. The procedures in Section 6.2.1 are to be followed.

6.3 Conducting Bird Surveys

6.3.1 Monitoring Schedule

In 2016, bird surveys are to be conducted from April 16 to October 31, inclusive. The mid-season break, nominally separating the spring and fall migratory periods, has been eliminated.

Monitoring will be conducted at each survey station three times per week, but should not be conducted over three consecutive days. A minimum of one day between surveys at a station should be scheduled. Monitoring at a station on consecutive days should only occur in response to special circumstances, primarily access restrictions.

If a scheduled bird survey is missed, due to temporary lack of access, weather, or other circumstances, it is to be rescheduled for later in the day or for the next available day. An attempted but unsuccessful survey is to be recorded as a missed survey, with comments indicating the reason that the survey could not be completed.

The comparison day has been eliminated from the 2016 protocol, as there are more opportunities during the week to make up for missed surveys. Only one survey per day is permitted, regardless of the number of times a survey has been missed at a station in a week,

6.3.2 Recording Landed Birds

6.3.2.1 Bird Survey Equipment

Each bird survey crew will carry the following survey equipment:

- binoculars ($\geq 10\times 42$ magnification);
- spotting scope ($\geq 60\times$ magnification) of sufficient quality to permit identification of birds at a distance of 500 m;
- tripod (panning head, ≥ 170 cm tall);
- electronic tablet or equivalent with the bird survey data form;
- notebooks (e.g., Rite-in-the-Rain®) and pencils;
- rangefinder (range of at least 500 m; may be integrated with binoculars);
- handheld GPS; and
- compass (with the magnetic declination set to 14° East in 2015).

Crews may add to this list at their discretion (e.g., bird identification guides).

6.3.2.2 Census-based Survey

One or more observer(s) can conduct a bird survey. Observers may conduct the survey from outside the vehicle, if safe, or inside the vehicle (e.g., strong winds or precipitation hamper detection outside the vehicle) providing that the entire survey area is visible and that the appropriate optics can be properly used from within the vehicle.

All landed birds within the survey area at the time of crew arrival at the survey station are to be counted and identified to the most precise level possible – at a minimum, identification to foraging guild is required (species of conservation concern are listed in Appendix A). Birds flushed from the survey area are to be counted, including those flushed on arrival of the crew at the survey station providing that the habitat(s) from which the birds were flushed can be identified. Birds landing in the survey area while observers are conducting the survey are also to be counted, however, birds landed at the time of crew arrival are to be characterized separately from those landing in the survey area during the survey.

A minimum survey duration of 5 minutes is required. If a large number of birds are present in the survey area, then a crew is to extend the survey beyond the 5-minute minimum time requirement to record and identify all birds. Once all birds are identified and counted, and the 5-minute minimum time requirement is met, the survey is to be concluded. However, if birds are landing continuously and without an obvious break, the census is to stop after 30 minutes.

Birds flying over the survey area at any altitude are not to be recorded.

An interruption during a census (e.g., weather delay, interruption by site activities) invalidates the bird survey, and the data form is to be deleted. The survey is to be rescheduled for later in the day or on the next available day.

Oiled birds are to be characterized according to the extent of oiling – trace, light, moderate, heavy or complete – and reported as required using site-specific procedures. Illustrations describing the levels of oiling are provided in Appendix B.

To better determine the outcome of an oiled bird observation, a greater emphasis on determining the end state of birds observed oiled by bird survey personnel is required in 2016. Within the constraints relating to safety and workflow, bird survey personnel are to determine the outcome of any oiled bird reports they make, and enter the end state (not recovered, recovered, outcome unknown) for those bird(s). This is to identify and address the possible double counting of oiled birds that would occur if each of the bird survey and mortality personnel independently record data on the same bird.

6.3.2.3 *Bird Survey Data Form*

The bird survey data form is presented in Table 7. As in previous years, electronic tablet forms will be configured and made available to site operators in advance of the initiation of monitoring. A data form is to be completed for each station on each day that a bird survey is scheduled for that LIF. If a survey cannot be completed at a survey station on a scheduled day, the missed survey field must be checked, and the comments field completed to describe the reason for not being able to conduct the survey.

The data form is to be saved on the tablet or equivalent at the completion of the bird survey. Data are to be reviewed and verified for accuracy by the observers before transmission to the database.

6.3.2.4 *Hazing*

If permitted within site-specific procedures, and it is safe to do so, observers may haze birds once a census is completed. An exception applies to a bird in immediate risk of contacting bitumen – in this instance observers are to immediately haze the bird (if permitted and safe to do so) to minimize the potential for bird oiling and possible mortality. Hazing during the survey invalidates the survey, and if the survey cannot be rescheduled, then notes must be made to indicate that hazing has occurred or is occurring to properly interpret the data.

Table 7: Bird Survey Data Form

| Tablet Field | Description |
|--|---|
| Submission ID | Field generated automatically when data entered into electronic database on the tablet |
| Operator | Operator Name |
| Date | Date of Survey |
| Observer 1 | Entered for each observer separately |
| Observer 2 | |
| Observer 3 | |
| Are you at the Survey Station | Yes or No; if no then a new survey station needs to be established and habitat form filled out, or this is a missed survey |
| Bird Survey or Missed Survey | Check box for either a bird survey (census) at the survey station, or if the survey station was missed on that day. If missed, the comment field must be completed to describe the reason for the missed survey |
| LIF Name | A drop down menu will be populated with the relevant LIF names upon entry of the operator field |
| Survey Station | The unique code assigned to each Survey Station |
| UTM Easting | Location of observation if barcode not scanned. A 6-digit entry is required |
| UTM Northing | Location of observation if barcode not scanned. A 7-digit entry is required |
| Percent Open Water (within Survey Area) | The amount of Open Water (includes floating bitumen mat area; excludes areas of emergent vegetation) within the Survey Area is estimated to the nearest percent |
| Start Time | Enter times in hh:mm:ss format (24-hour clock). Minimum survey time is 5 minutes |
| End Time | |
| Birds Observed | Yes or No; allows tracking of survey effort when no birds are observed |
| New Migrant, Migrant Seen Previously, or Resident | New Migrant, Migrant Seen Previously, Resident (with chicks or seen often), or Unknown – determined by bird behaviour, date of observations, presence of young birds, and occasionally by species; Residents are best identified from territorial or nesting behaviour and are most likely from mid-May to end-July, but can occur earlier or later depending on species |
| Species or Group | Species name, or if species unknown then group name (i.e. UNK_GREBE, UNK_DUCK, UNK_DABBLER, etc.); all birds that land are to be recorded regardless of guild; a new entry will be created for each landed bird group. A bird group is defined as a group of birds that all share the same information such as migrant or resident, same species, landed at start, substrate where landed, and oiling level. If one or more of these characteristics differ, a new entry must be made for the bird(s) |
| Guild | Field populated automatically when data entered into Species or Group (i.e. Dabbler, Diver, Wader, Gull, Scavenger, Other) |
| Was the Bird(s) Present when the Survey Started | Yes or No |
| Did you see the Bird(s) Land after the Survey Started | Yes or No. Used to identify which birds fly into the survey area and land during the census |

| Tablet Field | Description |
|---|---|
| Substrate Where Bird Landed | Open Water, Flat/Bank Vegetated, Emergent Vegetation, Island Vegetated, Flat/Bank Non-vegetated, Island Non-vegetated, Bitumen Mat, Artificial Structure or Materials, Other (Other should be used if substrate is woody debris or flooded upland, comments are required) |
| Number of Adults and Flight-capable Juveniles | The number of flight-capable landed birds of each species or species group |
| Number of Chicks | This field is only used when young birds that are incapable of flight are present; otherwise this field will remain blank |
| Number of Oiled Birds | The number of oiled birds including adults and young birds of each species or group |
| Bird Oiling Level | Trace: (<5%) small spots, bird apparently unaffected |
| | Light: (6 to 20%) oiling around top of legs, small spots or fine streaks on breast, head, or side; bird still capable of sustained flight |
| | Moderate: (21 to 40%) including the belly, and some of the breast or vent; bird exhibits excessive preening, dunking in water, or other unusual behaviour; sustained flight likely compromised |
| | Heavy: (>40%) including the breast, belly, and maybe the face; the bird is incapable of flight or easily captured |
| | Complete: completely oiled |
| Bird End State | Not Recovered, Recovered, Unknown |
| Surface Bitumen Present | None, Floating, Waterline, Ground, Objects; floating bitumen may be observed on open water and away from shore, bitumen can also be found along the edge of the water or Waterline, and on the Ground away from the water, and/or on Objects (e.g., boom, container, woody debris) |
| Surface Bitumen Amount (% of Survey Area) | None: 0% |
| | Very Low: 1 to 10% |
| | Low: 11 to 25% |
| | Moderate: 26 to 50% |
| | High: 51 to 75% |
| | Very High: 76 to 100% |
| Survey Area Visibility | Good: the survey area is clearly observed |
| | Partially Reduced: heat shimmer, light precipitation or wind, and sun glare reduce visibility; all birds within the survey area can be confidently counted, some identifications may be compromised |
| | Significantly Reduced: heavy precipitation, large waves, dense steam, smoke, or fog causing some birds in the survey area to not be seen. If this option is chosen, then comments are required to indicate the visible distance |
| Activity Affecting Bird Numbers in the Survey Area | Operations, Traffic, Construction, Intermittent Noise, Deterrent Activation, Deterrents Have Moved, Deterrents are being Maintained, Hazing Before Survey, Hazing During Survey; subjective judgement based on the activities near or in a survey area that will affect the number of birds landed, more than one activity can be entered |
| Comments | Comments about constraints affecting the ability to conduct a survey at a station; describe why a LIF or station was not surveyed as scheduled; significant visibility restrictions and visible distance; other observations at discretion of survey crew |

7.0 MORTALITY SEARCHES

7.1 Overview of the Mortality Search Procedure

The mortality search component of the Protocol applies to the LIFs determined to have a High Bird Mortality Risk.

Migrant and resident waterbirds are at risk of bitumen contact, and hence mortalities may occur anytime during non-frozen water conditions. As in previous years, the 2016 mortality search schedule is based on the typical open water season, from April 16 to October 31, inclusive. Mortality searches are recommended following severe weather, particularly after days when a sudden decrease in temperature, freezing rain, and heavy fog occur in combination. Mortality searches can be conducted at any time during daylight hours.

Three types of searches are included in the mortality search procedure: (1) transect searches conducted either concurrently with other activities or targeting areas where bitumen accumulates and/or bird mortalities have been observed previously (2) fixed-radius scans of areas where transect methods are not appropriate and where bird oiling and mortality risks are higher, in preferred habitats where birds are known to accumulate, along booms, near outflow pipes, and/or areas that may not be amenable to transect search methods, and (3) small LIFs where scans of the entire LIF surface can be completed. Although few oiled, live and dead birds are found during fixed-radius scan and small LIF searches, these procedures are valuable in performing a mortality search when it is not possible to conduct a transect search.

Oiled, live and dead birds located outside of formal search procedures are to be recorded as incidental observations.

The evolution of the mortality search procedures is presented in Table 8.

7.2 Mortality Search Types

Three types of mortality searches may be conducted: (1) transect searches, (2) fixed-radius scans, and (3) small LIF searches. All three include recording of effort, measured by the area searched within which dead birds can be confidently identified. Transect searches are preferred, however, fixed-radius scans and/or small LIF searches may be conducted at LIFs where it is not possible to conduct a transect search.

Mortalities may be discovered as part of site operations unrelated to the OSBCMP procedures. Personnel receiving information on these discoveries are to gather and record these incidental observations using the appropriate data form.

7.2.1 Transect Search

Bird mortalities are often found during deterrent maintenance and bird hazing activities. The transect method is designed to capture as much effort as possible during the majority of on-pond activities associated with the discovery of oiled, live and dead birds.

Table 8: Evolution of the Mortality Search Procedures (2013 to 2016)

| Item | 2013 (St. Clair et al. 2013) | 2014 (St. Clair et al. 2014) | 2015 (OMEI 2015) | 2016 |
|--------------------------------|--|--|---|------------|
| Mortality data forms | Recorded mortalities in a separate database via computer following collection of field notes | Forms for each search type; homogenized the provincial and Protocol requirements | Standardized forms to be used to record mortality observations and live oiled bird observations, and the search effort associated with each | As in 2015 |
| Search timing | Conduct mortality searches during spring and fall migration periods (April 16 to July 6 and July 25 to October 31). Mortality searches can be conducted at any time during the day | As in 2013 | Mortality searches from April 16 to October 31, inclusive. Mortality searches can be conducted at any time during the day | As in 2015 |
| Frequency | Visit each designated mortality transect at each LIF once every two weeks, and at the operator's discretion | As in 2013 | Each LIF with a High Bird Mortality Risk is to be searched once in every 10-day period during the monitoring season | As in 2015 |
| Methods | Combination of route-based and focused searches | Combination of route-based and focused searches with increased emphasis on standardization | Combination of transects, fixed-radius scans and small LIF searches at LIFs with High Bird Mortality Risk, with increased emphasis on recording search effort | As in 2015 |
| Data submission | Submitted data only via tablets or web-based forms; recommended use of paper data forms only on an interim or emergency basis | Recommended data entry in real time to support measurement of search time; entered data transmitted to the data manager in a separate step | Data to be submitted electronically, at a minimum weekly | As in 2015 |
| Data QA/QC | University of Alberta error-checked data weekly and sent requests to operators | Designated an entity to ensure data QA/QC occurred frequently (ideally weekly) | Daily data QA/QC, and at a minimum, weekly submission of electronic data to data manager. Data returned to crew for QA/QC at 2-week intervals | As in 2015 |
| Mortalities per unit of effort | Mortalities per km searched per LIF per year | Mortalities per km searched, per area searched, and/or per hour searched, per LIF per year | Mortalities per ha per LIF per year, by habitat type to the extent permitted by the data | As in 2015 |
| Reporting | Operators wrote reports for their site; the University of Alberta compiled a report for comparison across sites | Recommended comparison of data across operators with compiled data and figures for analysis | Data submitted to Program Manager for compilation and regional reporting | As in 2015 |

All travel by boat can be considered a transect, and providing speed of travel permits reliable identification of an oiled, live or dead bird within an estimated distance to each side of the boat, the transect may be considered a mortality search. Thus, crews conducting deterrent maintenance, hazing, bird capture and other watercraft-based activities may conduct valid mortality searches as a component of their activities, providing that distance travelled and effective search width is recorded, and crews conduct an effective search of the defined area.

To conduct a valid transect search, both distance travelled and a visible strip width must be recorded. Visibility during transect searches is influenced by weather conditions, wave action, terrain and vegetation, and other view obstructions, and these must be considered in defining the visible, searched strip width. A maximum visible strip width of 50 m (25 m either side of a transect) on open water is the most reasonable distance in which an oiled dead bird can confidently be seen (OMEI 2016), and shorter distances may be applied. Oiled live birds can be observed at further distances, but the effort calculations are limited to the ability to locate oiled dead birds. Transects conducted in vegetated habitats are expected to have reduced visibility, often as low as a few metres.

Shore-based transects conducted on foot or by ATV (i.e., around the perimeter of a LIF) are valid, and contribute to meeting mortality search target distances (see below). Because few avian mortalities can be reliably detected from within a truck, and definition of a visible search width is difficult, mortalities observed from a truck are to be recorded as incidental observations without information on search effort.

It is preferable to use hand-held GPS units to record transects conducted as mortality searches, however, GPS units may not be permitted at all LIFs. For those LIFs at which GPS units (or equivalent) cannot be used, images of LIFs with UTM grids (at 50 m to 500 m intervals, depending on LIF size) are to be prepared (by April 16) for use by the mortality search crews. Information necessary for the crew (docks, LIF and open water access points, effluent outfall structures, booms) and areas to be targeted during mortality searches, including areas that potentially contain bitumen, is to be shown on the LIF images.

Habitat will be described within the search area (open water, bitumen mats, flats/banks, etc.), and the percent of each habitat type will be estimated.

7.2.2 Fixed-Radius Scan

Fixed-radius scans are to be used when access precludes the ability to search an area by the transect method. Fixed-radius scan locations will target areas where bitumen is known to accumulate and areas with habitats attractive to birds, and be chosen to maximize visibility. Locations where vegetation is present, bitumen accumulates, or birds are routinely present are candidates for locations for fixed-radius scans. Areas identified through the season as High risk of bird mortality should also be searched. Preliminary locations from which fixed-radius scans are to be conducted are to be identified by April 16, the start of monitoring, and can be adjusted as appropriate through the season.

A fixed-radius scan is conducted from a single location (UTM coordinates recorded, or estimated by map grid coordinates), with the search radius fixed as the maximum distance within which an oiled dead bird can be reliably detected. The searchable area will be measured using a compass and rangefinder. Two compass bearings will be taken, one each representing the left side and right side limits of the field of view (Figure 5). The angle of the view (the fixed-radius) and area searched will be derived from these bearings during data processing.

Habitat will be described within the search area (open water, bitumen mats, flats/banks, etc.), and the percent of each habitat type will be estimated. Vegetated habitats are to be included, however, the effective distance in which a dead bird can be seen is significantly reduced in these habitats, unless the vegetation is sufficiently sparse to see through the foliage to the ground. Mortality searches conducted using a fixed-radius scan will document obstructions and other limitations that may prevent a dead bird from being discovered at the time of the search.

7.2.3 Small LIF Searches

The small LIF search method may be used when access precludes the ability to search a LIF by the transect method. This method is only appropriate when the entire LIF may be searched from one or a few locations, and searchers are confident that they are able to identify dead, oiled birds anywhere in the LIF. If the LIF is too large to allow this requirement to be met, the small LIF procedure is not appropriate, and one or more fixed-radius scans should be conducted instead.

No survey effort information is recorded, as the area of the LIF will be known from image analysis by GIS, or other in-field measurements.

7.3 Mortality Search Effort

The following is provided for guidance to operators in designing their mortality search effort on LIFs having a High Bird Mortality Risk. In every 10-day period beginning on April 16:

- transect searches conducted by watercraft are to cover 15% of the total open water area of each tailings facility and large LIF, using the open water areas reported in the 2015 OSBCMP Regional Report. A visible search width of 50 m (25 m on each side of the watercraft, based on distance of detections of deceased birds from moving watercraft (OMEI 2016) is to be used to calculate the distance to be searched;
- fixed-radius scans conducted where transects are not possible. Based on distances recorded in 2015, heavily oiled birds could be seen from a fixed location at distances of about 15 m, and this limitation must be recognized by survey personnel such that the search distances are not inappropriately overestimated. Fixed-radius scans should be conducted from a number of observation points, separated by a minimum of 50 m, along the LIF edge; and/or
- complete area search of small LIFs, where transect searches cannot be conducted.

Figure 5: Fixed-radius Mortality Search Delineation

Quantifying the distance at which dead birds are detected is a goal of the mortality search program. For this reason, it is critical that upon confirmation that a detected object is an oiled live bird or mortality, the crew immediately measures or estimates the distance to the bird, preferably using a rangefinder, regardless of whether the bird is within or outside of the defined search area (no adjustment to the search area is necessary). This detection distance will be used in evaluations of detectability, supporting Protocol evolution and the ability to achieve program objectives.

7.4 Data Collection

Consistent recording of search effort is critical to data analysis and interpretation. Recording search effort is especially important when no oiled dead birds are found because these records contribute to the analysis of the number of birds found per unit area searched.

Data will be entered on mortality search forms (Table 9) using electronic tablets, their equivalent, or on paper for later entry into the mortality database. Incidental observations of oiled, live and dead birds, those which cannot be associated with search effort, are to be entered into a separate form. Data are to be submitted electronically, preferably by the end of the daily work shift but at a minimum of every week.

Crews assigned mortality search responsibilities will carry the following equipment:

- binoculars (10x42 magnification or greater);
- compass;
- tablet for data entry or clip board with paper data sheets; and
- hand-held GPS (or equivalent) or laminated map with UTM grid (if map, then include erasable marker).

A rangefinder (range of at least 500 m; may be integrated with binoculars) is recommended for use by mortality search crews, however, alternate distance measurements are permitted (e.g., two GPS points from which distance can be derived).

Oiled birds are to be characterized according to the extent of oiling – light, moderate, heavy or complete – and reported as required using site-specific procedures. Illustrations describing the levels of oiling are provided in Appendix B.

To better determine the outcome of an oiled bird observation, a greater emphasis on determining the end state of birds observed oiled by other personnel is required in 2016. Within the constraints relating to safety and workflow, mortality search personnel are to determine whether or not observed birds, including those captured, have also been entered into other data forms (e.g., bird survey). Both teams are to work towards ensuring that their respective datasets are complete, that notes are made reflecting that the bird(s) have been recorded in other database(s), and that the bird end state is consistently entered. This is to identify and address the possible double counting of oiled birds that would occur if each of the mortality search and bird survey personnel independently entered data on the same bird.

Table 9: Mortality Search Data Form

| Tablet Field | Description |
|--|--|
| Submission ID | Field generated automatically when data entered into electronic database on the tablet |
| Operator | Operator name |
| Date | Date of Search |
| Searcher 1 | Entered for each searcher separately as a source of information if there are questions on data |
| Searcher 2 | |
| Searcher 3 | |
| LIF Name | Consistent with site LIF Name; a list of LIF names is to be provided by the site operator to populate a drop down menu |
| Activity During Search | Designated Search, Maintenance, Bird Hazing, Other (comments required) |
| Type of Search | Transect, Fixed-radius, or Small LIF |
| Percent of Habitat in Search Area | Open Water, Flat/Bank Vegetated, Emergent Vegetation, Island Vegetated, Flat/Bank Non-vegetated, Island Non-vegetated, Bitumen Mat, Artificial Materials (including structures), Other (includes woody debris and flooded upland, comments required). Should add to 100% |
| Start time | Start time of search in hh:mm:ss format (24-hour clock) |
| End time | End time of search (hh:mm:ss format; 24-hour clock); interruption in a search should be described in the comments |
| To Be Completed for a Transect Search | |
| Search Method | Walking, Boat, ATV, Other (comments required) |
| Search Start UTM Easting | Starting location of Transect |
| Search Start UTM Northing | |
| Search End UTM Easting | Ending location of Transect |
| Search End UTM Northing | |
| GPS Track File Name | File name of GPS track of Transect (optional if distance is calculated or estimated and entered into the tablet) |
| Distance (m) | Distance travelled on a Transect; calculated from a GPS or estimated from a UTM grid on a map |
| Was Distance Estimated or Calculated? | Estimated or Calculated distance of a Transect; estimates can be used if determined from a UTM grid on a map and will be reflected in a lower level of confidence in the analyzed data |
| Visible Distance Left (m) | Distance to left side of transect with good visibility and within which a dead bird can be reliably detected, will be within meters of either side of a transect and can be estimated if within 25 m |
| Visible Distance Right (m) | Distance to right side of transect with good visibility and within which a dead bird can be reliably detected, will be within meters of either side of a transect and can be estimated if within 25 m |
| To Be Completed for a Fixed-radius Scan | |
| Search Location UTM Easting | Point location of Fixed-radius scan |
| Search Location UTM Northing | |
| Visible Range Fixed-radius (m) | Effective distance of observation with good visibility and within which a dead bird can be reliably detected; distance can be estimated if less than 25 m and will be measured by a range finder if distance is further |
| Left Bearing Fixed-radius Scan | The left compass bearing best representative of the visible search area as measured from a stationary observation point |
| Right Bearing Fixed-radius Scan | The right compass bearing best representative of the visible search area as measured from a stationary observation point |

| To Be Completed for a Small LIF | |
|---|--|
| Search Location UTM Easting | Location of Search |
| Search Location UTM Northing | |
| To Be Completed for all Birds Found During a Search | |
| Bird(s) Found | Yes or No; allows tracking of search effort when no birds are found |
| Species or Group | Species name, or if species unknown then group name (i.e. UNK_GREBE, UNK_DUCK, etc.). A bird group is defined as a group of birds that all share the same information such as migrant or resident, same species, landed at start, substrate where landed, and oiling level. If one or more of these characteristics differ, a new entry must be made for the bird(s) |
| Guild | Field populated automatically when data entered into Species or Group (i.e. Dabbler, Diver, Wader, Gull, Scavenger, Other (comments required)) |
| Number of Birds | Enter the number of oiled live or dead birds found, does not include bird mortalities unrelated to bitumen contact |
| Time Bird(s) was Found | Time a bird was first found |
| Where Was Bird Found | Description of the area or substrate where the bird was found; for example, can be habitat (i.e. open water, bitumen mat, flat/bank vegetated or non-vegetated, etc.), or can be more specific to the location, such as a boat launch or other recognizable feature |
| Distance from Observer to Bird (m) | From point where the bird was first observed; can be visually estimated or estimated from a UTM grid on a map, or measured by a range finder |
| Bird UTM Easting | Location of the bird where it was first observed; can be estimated from UTM grid on map |
| Bird UTM Northing | Location of the bird where it was first observed; can be estimated from UTM grid on map |
| State of Bird When Found | Alive or Dead |
| Bird Oiling Level | Trace: (<5%) small spots, bird apparently unaffected |
| | Light: (6-20%) oiling around top of legs, small spots or fine streaks on breast, head, or side; bird still capable of sustained flight |
| | Moderate: (21-40%) including the belly, and some of the breast or vent; bird exhibits excessive preening, dunking in water, or other unusual behaviour; sustained flight likely compromised |
| | Heavy: (>40%) including the breast, belly, and maybe the face; the bird is incapable of flight or easily captured |
| | Complete: completely oiled |
| End State | Found Dead Recovered, Dead Not Recovered, Euthanized, Alive Lightly Oiled Bird Not Recovered, Alive Moderately/Heavily Oiled Bird Not Recovered |
| Bird Body Condition | Good, Injured, or Scavenged |
| Comments | Comments about weather or search conditions, or site characteristics potentially influencing bird mortality and search efficiency |

8.0 INCIDENTAL OBSERVATIONS

An oiled, live or dead bird detected outside of a formal bird survey or mortality search procedures is to be recorded using the incidental data form (Table 10). Only those birds that have contacted bitumen associated with process-water are to be recorded in the form. Bird mortalities that are not oiled are to be reported according site procedures and no data or information about these birds are to be entered into any of the data forms in this Protocol.

9.0 QUICK SCAN PROCEDURE

A subset of LIFs excluded from the bird survey and mortality search procedures (either by application of the exclusion criteria or by use of the risk model) are to be surveyed through the monitoring seasons using a quick scan procedure.

By April 16, operators are to identify and provide the names of LIFs to be included in the quick scan procedure. LIFs to be included in the quick scan procedure can be either on or within a short distance from the usual route taken by the bird survey and/or mortality search personnel in the daily course of the monitoring program.

9.1 Quick Scan Schedule

LIFs included in the quick scan procedure are to be searched a minimum of twice per week, from April 16 to October 31, inclusive. Quick scans can be conducted on any day and at any time during daylight hours.

9.2 Quick Scan Data Collection

The entire LIF (open water surface and surrounding habitats within the LIF boundary) is to be scanned. Quick scan data are to be entered into the tablet form (Table 11). There is no minimum time requirement associated with the effort of a quick scan search.

10.0 DATA ANALYSES AND REPORTING

Monitoring personnel are to review the accuracy and completeness of records at the end of each bird survey, habitat assessment, mortality search and quick scan, and correct or complete entries as appropriate prior to submission of the data into the program database. The following are to be confirmed by monitoring crews and site personnel during data review:

- LIF names, station names, and UTM coordinates must be checked to confirm that they apply to the proper survey location;
- survey start and end times are correct and are within the appropriate survey duration;
- comments entered to reflect unique circumstances affecting data interpretation;
- duplicate bird entries are clearly identified by comments; and
- data entries are correct to the best knowledge of the monitoring crews collecting the data.

Table 10: Incidental Data Form

| Tablet Field | Description |
|--|---|
| Submission ID | Field generated automatically when data entered into electronic database on the tablet |
| Operator | Operator Name |
| Date | Date of Survey |
| Monitoring Crew | Bird Survey Crew, Mortality Search Crew, Other |
| Observer 1 | Entered for each observer separately. Observer names are to be provided by the site operator to populate the dropdown menu keyed to the monitoring crew |
| Observer 2 | |
| Observer 3 | |
| Incidental | Field is automatically generated when the form is opened. All incidental observations are also to be recorded using this form |
| UTM Easting | Location of observation when oiled bird is first observed. A 6-digit entry is required |
| UTM Northing | Location of observation when oiled bird is first observed. A 7-digit entry is required |
| Is the Incidental Associated with a LIF? | Yes or No; If Yes is selected a drop down menu will be populated with the relevant LIF names upon entry of the operator field (do not use codes or abbreviations); a list of LIF names is to be provided by the site operator to populate the drop down menu keyed to the operator name. If No, then the location has to be entered into comments |
| Location Comments | Comments about the location can be entered here |
| To Be Completed for all Birds Found Incidentally | |
| New Migrant, Migrant Seen Previously, or Resident | New Migrant, Migrant Seen Previously, Resident (with chicks or seen often), or Unknown – determined by bird behaviour, date of observations, presence of young birds, and occasionally by species; Residents are best identified from territorial or nesting behaviour and are most likely from mid-May to end-July, but can occur earlier or later depending on species |
| Species or Group | Species name, or if species unknown then group name (i.e., UNK_GREBE, UNK_DUCK, UNK_DABBLER, etc.); all oiled birds, alive or dead, that are incidentally found are to be recorded regardless of guild. A bird group is defined as a group of birds that all share the same information such same species, substrate where landed, and oiling level. If one or more of these characteristics differ, a new entry must be made for the bird(s) |
| Guild | Field populated automatically when data entered into Species or Group (i.e., Dabbler, Diver, Wader, Gull, Scavenger, Other (comments required)) |
| Number of Adults and Flight-capable Juveniles | The number of flight-capable landed birds of each species or species group |
| Number of Chicks | This field is only used when young birds that are incapable of flight are present; otherwise this field will remain blank |
| Time Bird(s) was Found | Time an oiled bird was first found; includes alive or dead birds, does not include birds with no bitumen contact |
| Substrate Where Bird was Found | Open Water, Flat/Bank Vegetated, Emergent Vegetation, Island Vegetated, Flat/Bank Non-vegetated, Island Non-vegetated, Bitumen Mat, Artificial Structure or Materials, Other (Other should be used if substrate is woody debris or flooded upland, comments are required) |

| | |
|---|---|
| State of Bird When Found | Alive or Dead |
| Bird Oiling Level | Trace: (<5%) small spots, bird apparently unaffected |
| | Light: (6-20%) oiling around top of legs, small spots or fine streaks on breast, head, or side; bird still capable of sustained flight |
| | Moderate: (21-40%) including the belly, and some of the breast or vent; bird exhibits excessive preening, dunking in water, or other unusual behaviour; sustained flight likely compromised |
| | Heavy: (>40%) including the breast, belly, and maybe the face; the bird is incapable of flight or easily captured |
| | Complete: completely oiled |
| End State | Found Dead Recovered, Dead Not Recovered, Euthanized, Alive Lightly Oiled Bird Not Recovered, Alive Moderately/Heavily Oiled Bird Not Recovered |
| Bird Body Condition | Good, Injured, or Scavenged; to be used to determine if other evidence of injury or scavenging has occurred |
| Add Another Species or Species Group | Yes or No |
| Comments | Comments at discretion of monitoring crew |

Table 11: Quick Scan Data Form

| Tablet Field | Description |
|--|--|
| Submission ID | Field generated automatically when data entered into electronic database on the tablet |
| Operator | Operator Name |
| Date | Date of Survey |
| Observer 1 | Entered for each observer separately |
| Observer 2 | |
| Observer 3 | |
| LIF Name | A drop down menu will be populated with the relevant LIF names upon entry of the operator field |
| Start Time | Enter times in hh:mm:ss format |
| End Time | |
| Birds Observed | Yes or No; allows tracking of survey effort when no birds are observed |
| New Migrant, Migrant Seen Previously, or Resident | New Migrant, Migrant Seen Previously, Resident (with chicks or seen often), or Unknown – determined by bird behaviour, date of observations, presence of young birds, and occasionally by species; Residents are best identified from territorial or nesting behaviour and are most likely from mid-May to end-July, but can occur earlier or later depending on species |
| Species or Group | Species name, or group name if species unknown (i.e. UNK_GREBE, UNK_DUCK, UNK_DABBLER, etc.); all birds that land are to be recorded regardless of guild. A bird group is defined as a group of birds that all share the same information such as migrant or resident, same species, landed at start, substrate where landed, and oiling level. If one or more of these characteristics differ, a new entry must be made for the bird(s) |
| Guild | Field populated automatically when data entered into Species or Group (i.e. Dabbler, Diver, Wader, Gull, Scavenger, Other) |
| Substrate Where Bird Landed | Open Water, Flat/Bank Vegetated, Emergent Vegetation, Island Vegetated, Flat/Bank Non-vegetated, Island Non-vegetated, Bitumen Mat, Artificial Structure or Materials, Other (Other should be used if substrate is woody debris or flooded upland, comments are required) |
| Number of Adults and Flight-capable Juveniles | The number of flight-capable landed birds of each species or species group |
| Number of Chicks | This field is only used when young birds that are incapable of flight are present; otherwise this field will remain blank |
| Number of Oiled Birds | The number of oiled birds including adults and young birds of each species or group |
| State of Oiled Birds When Found | Alive or Dead |
| Bird Oiling Level | Trace: (<5%) small spots, bird apparently unaffected |
| | Light: (6-20%) oiling around top of legs, small spots or fine streaks on breast, head, or side; bird still capable of sustained flight |
| | Moderate: (21-40%) including the belly, and some of the breast or vent; bird exhibits excessive preening, dunking in water, or other unusual behaviour; sustained flight likely compromised |
| | Heavy: (>40%) including the breast, belly, and maybe the face; the bird is incapable of flight or easily captured |
| End State | Complete: completely oiled |
| End State | Found Dead Recovered, Dead Not Recovered, Euthanized, Alive Lightly Oiled Bird Not Recovered, Alive Moderately/Heavily Oiled Bird Not Recovered |
| Bird Body Condition | Good, Injured, or Scavenged |

| | |
|--|---|
| Surface Bitumen Present | None, Floating, Waterline, Ground, or Objects; floating bitumen may be observed on open water and away from shore, bitumen can also be found along the edge of the water or Waterline, on the Ground away from the water, and/or on Objects (e.g., boom, container, woody debris) |
| Surface Bitumen Amount (% of Survey Area) | None: 0% |
| | Very Low: 1 to 10% |
| | Low: 11 to 25% |
| | Moderate: 26 to 50% |
| | High: 51 to 75% |
| | Very High: 76 to 100% |
| Comments | Provide any comments if warranted |

Estimates of bird contacts (landings) within survey areas and associations between bird observations (number and species) and habitats are useful in support of site management practices.

An estimate of bird landings by habitat type per hectare per day will be determined for each survey area. The area of each survey area will be calculated from a combination of GIS analyses and ground-level habitat characterization. An estimate of bird mortalities per unit area of effort will be determined.

Numerous factors affect the ability to detect oiled, dead birds, including habitat, visible range and bird condition. To the extent possible, the habitat in which the mortality was detected is to be recorded. These data will not be used to derive habitat-specific mortality estimates; rather, it these habitat associations may provide insight into detectability of oiled, dead birds.

The Program Manager will prepare the regional report, and coordinate with operators the preparation of the site-specific documents that will meet the requirements of their individual approvals, authorizations and bird/waterfowl/waterbird protection plans.

Appendix B

U.S. Fish & Wildlife Service (2010)

Characterization of Bird Oiling Levels

NRDA Bird Oiling Levels

TRACE

Note single tiny spot or fine streak on breast, face, or side.

Typically a single to several tiny spots or hairline streaks.

LIGHT

Note light soiling around the top of leg(s).

Other example of light oiling may also appear as light colored spots on the face or breast or belly, or parts of the body. Oiling on 2 or more body parts is recorded as Moderate.

MODERATE

Note that the whole belly is covered with moderately darker oil

Another example of moderate oiling showing most of the breast, belly and vent covered with oil.

HEAVY

Note that the breast and belly are covered with a very dark layer of oil.

Here, a heavy dark layer of oil is seen on the face, breast, and belly.

Bird Oiling Levels using Piping Plover as an example (extracted from U.S. Fish & Wildlife Service 2010)
